00 PROLOGUE

We Stand at Another Crossroads in the History of Computing

Once, computers were vast, expensive, and scarce machines.

They were housed in the computing centers of universities, government agencies, and large corporations. Individuals who wanted to use computing power often had to depend on the equipment, time, and access permissions that institutions provided.

At the time, no one could be entirely certain what form computers would take in human society. They might become infrastructure for scientific research, administration, and economic planning by large organizations, or they might gradually enter the work and everyday lives of ordinary people.

In the 1970s, advances in microprocessors, the creativity of electronics engineers, and experiments by enthusiast communities such as the Homebrew Computer Club helped bring a different future into being.

They believed that computers need not remain expensive resources controlled by a handful of institutions forever. People could own their own computers, write their own programs, save their own files, and decide, according to their own imagination, what to use their computers for.

The personal computer revolution began.

It changed not only the size and price of computing devices, but also the relationship between computing power and the individual.

> **Computing was no longer merely a tool for organizations to manage the world. It also became a tool for individuals to understand and create the world.**

Today, half a century later, artificial intelligence confronts us with a similar historical choice.

Increasingly powerful models are gaining the ability to understand language, process information, write programs, use tools, and even carry out tasks on people's behalf.

Yet most of these capabilities are delivered through vast computing centers, cloud services, and internet platforms. Meanwhile, the data that offers the greatest continuity and interpretive value in a person's life remains scattered across phones, computers, private storage devices, social platforms, and countless isolated applications.

Each of us is producing an increasingly complete digital history, yet we may lack the full capacity to put that history to use.

We can use increasingly powerful artificial intelligence, yet we may be unable to decide how it understands us, how it accesses our information, or what actions it takes on our behalf.

This creates a defining contradiction of our time:

> **The capabilities of artificial intelligence are growing rapidly, but individuals' effective control over their own digital lives is not growing at the same pace.**

We believe this situation should not be accepted as an inevitable outcome of technological development.

If the previous personal computer revolution gave ordinary people the ability to run programs independently, the aim of a new revolution should be to give ordinary people the ability to organize, deploy, and constrain artificial intelligence on their own terms.

We call this historical possibility:

> **The PC Moment of AI.**

We hope to help bring this moment into being.

01 CHAPTER ONE

What We Seek Is More Than a Machine

When personal computers first emerged, a single physical computer could serve as the center of a person's computing activities.

But in the age of artificial intelligence, the physical boundaries of computing systems are becoming blurred.

A person's computing power may come from a phone chip or from high-performance computing equipment at home; it may come from a public cloud platform or from a model service running in a distant data center.

Likewise, the data a person needs to process is not always held together on a single hard drive.

It may consist of photographs, documents, and correspondence accumulated over many years, creative materials not yet organized, or information about events and behavior continuously generated by different devices in everyday life.

We therefore do not believe that the next generation of personal computers must be a machine with a fixed physical enclosure.

The personal computer we envision is, first and foremost, **a human-centered way of organizing computing**.

In this way of organizing computing:

- Data can be discovered, understood, and used with authorization, without all of it having to be stored in one place.
- Compute can be obtained from different sources according to the needs of a task, without being tied to a single model provider.
- AI Agents can carry out tasks on individuals' behalf, but their power must be explicitly constrained.
- Individuals can inspect and correct their AI systems, withdraw their authority, and migrate them without having to rebuild their digital lives from scratch.

We call this technological system **Personal AI Computing**.

It may run on a home server or consist of several devices working together; it may call cloud models or run entirely locally.

What truly defines it is not where computation takes place, but **who can determine its purpose, scope, and boundaries**.

We do not oppose cloud computing or large models, nor do we believe that everyone needs to own an expensive GPU.

On the contrary, we welcome public computing facilities, commercial model services, open-source software, and a diverse hardware ecosystem.

What we oppose is making the convenience of using these technologies inseparable from surrendering personal control.

Models can be rented as services, and compute can be accessed across networks.

But a person's long-term memory, personal relationships, and digital life should not thereby become appendages of a platform from which they cannot be moved.

> **We maintain that computing resources may be distributed, but individuals' ultimate authority to grant authorization must not be dispersed and lost along with them.**

02 CHAPTER TWO

Personal AI Sovereignty

We use the word "sovereignty" not to claim that individuals can be free of the constraints of law, social relationships, or the rights of others.

We use it to describe a more specific set of technical and social rights:

Individuals have the ability to decide what purposes their AI systems serve, what resources they use, what information they disclose, and under what conditions they act.

Today, many services allow users to choose whether to agree to a privacy policy, yet few allow users to truly decide how their data works together across different services.

Users can close an account, yet may be unable to fully migrate the behavioral history and personal context they have accumulated over many years.

Users can call on AI, yet may be unable to adequately inspect the paths through which AI accesses their data.

We believe the next generation of Personal AI Infrastructure should be founded on the following rights.

> **I. The right to choose one's computing.**

Within technical and legal limits, users should be free to choose local models, remote models, and computing devices without being permanently bound to a single provider.

> **II. The right to migrate one's AI context.**

Wherever possible, the memories, preferences, knowledge indexes, and authorization settings that individuals accumulate over time should use formats that can be exported and converted. Changing models should not mean losing one's digital history.

III. The right to control data disclosure.

The data needed to complete a task should be constrained by purpose, scope, and recipient. Authorization to access data on one occasion does not imply permission to retain it permanently, redistribute it, or use it for other purposes.

IV. The right to limit an agent's power.

AI may act on a user's behalf, but users must be able to limit its permissions, inspect consequential operations, revoke authorization, and stop it when necessary.

V. The right to explanation and correction.

When a system refuses a request, discloses information, or infers a user's preferences, it should be able, within reasonable limits, to provide an understandable explanation. Users should have a means of correcting mistaken inferences.

VI. The right to forget and begin again.

A person's past should not become an algorithmic dossier that binds them forever. Users should be able to delete memories they no longer need, rebuild their personal profiles, and decide which parts of their history should no longer influence future judgments.

VII. The right to a safe exit.

Users should be able to change providers, stop using a service, or leave an ecosystem without losing their core data and basic capabilities to technological lock-in.

These rights cannot be realized by a manifesto alone.

They must be built into software interfaces, data formats, identity mechanisms, authorization protocols, and the default behavior of real products.

Rights that ordinary users cannot exercise in practice can all too easily become rhetoric in the promotion of technology.

03 CHAPTER THREE

From Platforms Knowing Individuals to Individuals Understanding Themselves

Over the past two decades and more, internet platforms have developed sophisticated capabilities for analyzing user behavior and preferences through the continuous accumulation of data.

Search histories, geographic locations, purchase records, social networks, viewing time, and interaction patterns can help large platforms infer individuals' interests, habits, and potential needs.

These technologies have made life more convenient, but they have also created new asymmetries of power.

Platforms can come to know a user through vast amounts of data, while users struggle to access and use that information about themselves on comparable terms.

We believe artificial intelligence offers the possibility of changing this relationship.

Large platforms have the advantage of data at scale across large populations.

Individuals, however, have another potential advantage: long-term, continuous data about their own lives, direct knowledge of the context of events, and the authority to interpret their own goals and values.

A creative archive preserved for ten years, a record of learning sustained over many years, or a series of important life decisions may have little statistical value to others, yet hold unique meaning for the person to whom they belong.

If artificial intelligence can use these materials with individuals' authorization to help them revisit their experiences, understand their choices, organize their knowledge, and carry out future work, personal data may be transformed from a resource through which platforms extract commercial value into a resource through which individuals extend their capabilities.

We hope to advance this transformation.

But we must also recognize that understanding a person does not confer the right to decide for them.

An AI capable of understanding a user's life history may also form rigid judgments about their identity on the basis of outdated information, mistaken inferences, or biased training outcomes.

A personal AI system should therefore not become a digital guardian that claims to know users better than they know themselves.

It should help users form judgments, rather than monopolize judgment.

It should be able to remember, but also allow forgetting; be able to infer, but also acknowledge uncertainty; be able to offer advice, but not automatically acquire greater power because it holds more data.

> **Artificial intelligence should expand human autonomy, not replace it with a more precise personal profile.**

04 CHAPTER FOUR

The Personal AI Infrastructure We Envision

Achieving these goals will require far more than developing a smarter chatbot.

We need to explore general-purpose infrastructure that can operate over the long term, span devices, adapt to different computing environments, and maintain clearly defined security boundaries.

As a starting point, we propose five technical components that work together.

1. Personal Root of Trust: Who Has the Authority to Represent Me?

Every personal AI system should have trustworthy mechanisms for identity and authorization.

Devices, applications, AI Agents, and remote services should have distinguishable identities, rather than simply sharing an administrator account with all permissions.

The system needs to support secure pairing, device authentication, key rotation, permission revocation, and trusted recovery.

Hardware security modules, trusted execution environments, and modern cryptography can provide part of the foundation, but they should not become reasons to bind users permanently to a particular vendor.

The purpose of a Personal Root of Trust is to establish a mechanism that can answer these questions:

Who is making the request? Whom does it represent? What permissions has it been granted? When do those permissions expire?

2. Distributed Personal Data Layer: Data May Be Dispersed; Access Must Be Orderly

We do not advocate unconditionally copying all of a person's data into a central database.

That would create a dangerously concentrated target within the system.

Instead, original materials can remain on a NAS, personal computer, phone, cloud storage, or other authorized services.

Through open data connectors, metadata indexes, semantic retrieval, and access control mechanisms, the system provides unified capabilities for discovering and using data.

Where appropriate, computation should take place as close to the data as possible.

For example, a personal NAS can search private documents locally and provide an external model only with the information necessary for the task and authorized for disclosure, rather than uploading the entire document library.

In the longer term, we hope to explore personal knowledge structures that carry information about provenance, time, confidence, and access constraints, enabling the system to understand relationships between pieces of information while avoiding treating unverified AI inferences as objective facts.

3. Heterogeneous Compute Layer: The Task, Not the Model, Is at the Center

The model best suited to a user in the future will not always come from the same company, nor will it necessarily run in the same place.

The system should be able to discover and call upon on-device NPUs, local GPUs, home servers, community computing resources, and remote model APIs.

A unified task scheduler selects an appropriate execution path based on latency, cost, capability, energy consumption, privacy constraints, and device status.

Ordinary users do not need to understand the details of model deployment.

They need only express their goals and retain control over important constraints, such as "This task must be processed locally" or "Cloud models may be used, but the original audio recordings must not be sent."

We do not pursue local computing for its own sake.

> **Where personal control can be protected, enabling compute from different sources to collaborate freely is more meaningful than forcing all computation to take place on a single machine.**

4. AI Agent Execution Layer: Let Capabilities Collaborate, Not Permissions Proliferate

Each device and service can offer clearly defined capabilities to the system through standardized interfaces.

A NAS can provide restricted file retrieval services; a high-performance computing node can execute inference tasks; smart home devices can provide authorized control interfaces.

AI Agents should not receive full operating-system privileges on a device by default. They should use the smallest set of capabilities needed to complete the task.

Different tasks should receive separate, time-limited authorizations and carry out appropriate operations in isolated environments.

Open tool protocols, capability descriptions, revocable credentials, and auditable execution records should form the foundation of this layer.

We look forward to a time when connecting devices no longer means that they trust one another completely.

> **Collaboration should be built on explicitly granted capabilities, not on unrestricted network connectivity.**

5. Privacy and Authorization Layer: Let the System Understand Boundaries

We believe the main challenge of future privacy protection is not to have users label hundreds of thousands of files individually as "public" or "private."

Privacy in real life depends on context.

The same piece of information may be shareable in one task but should not be disclosed in another.

Personal AI systems therefore require research into privacy-assistance models capable of understanding data provenance, relationships between people, task purposes, and the potential consequences of disclosure.

Such a model can help identify sensitive information, propose ways to minimize disclosure, and explain the risks of an operation.

But we oppose making probabilistic AI inference an unquestionable supreme arbiter of permissions.

The actual enforcement of authorization should be handled by independent, explicit, and auditable policy mechanisms.

When a system cannot establish whether an operation accords with a user's intent, it should choose, according to the risk, to refuse it, limit its execution, or request confirmation.

A privacy AI Agent should ease the burden of managing complex permissions, rather than make all value judgments in the user's place.

05 CHAPTER FIVE

Security Is a Structure, Not a Wall

We must face an inescapable fact:

Organizing a person's photographs, recordings, documents, correspondence, social relationships, and long-term memories into a coherent whole that AI can use may create enormous personal value. It may also create unprecedented privacy risks.

A compromised personal AI system may expose not just a few files, but a highly continuous portrait of a person's life over time.

We cannot ignore this danger on the grounds that "the data is in the individual's hands."

Nor can we promise a system that is absolutely impossible to breach.

Any real-world hardware, software, supply chain, or management process may contain flaws.

We therefore advocate making **limiting the damage after a compromise** one of the core security objectives.

An untrusted device should not automatically gain access to core data simply because it joins a home network.

A compromised application should not easily obtain the secrets of other applications.

An AI Agent misled by malicious content should not be able to invoke high-risk tools unrelated to its current task.

The exposure of a single credential should not mean permanently losing control of an entire personal AI system.

To this end, we support Zero Trust networks, denial by default, the Principle of Least Privilege, task-level credentials, sandboxed execution, end-to-end encryption, secure boot, verifiable updates, independent backups, and continuous security auditing.

We also advocate treating backup and recovery, credential revocation after a device is lost, and the ability to migrate when a provider discontinues a service as basic functions of a personal computing system.

A truly secure product should demonstrate not only its ability to block attacks, but also its ability to recover after failures, compromises, and human error.

At the same time, security must not become a pretext for depriving users of control.

If a system claims that protecting users requires prohibiting them from exporting data, modifying software, examining permissions, or changing service providers, then that protection itself deserves scrutiny.

> **We seek a technical environment in which users can exercise their freedom safely, not a secure cage that decides everything for them.**

06 CHAPTER SIX

Personal AI Computing Is a Political and Technical Question

All infrastructure distributes power in one way or another.

Roads determine how people and goods move, power grids determine how energy is distributed, and communication networks determine the paths information can take and the places it can reach.

Computing infrastructure is no exception.

When individuals must go through a handful of platforms to obtain computing power, AI services, and access to personal data, those platforms acquire significant power to shape individuals' digital lives.

This does not mean that large corporations and public institutions are inherently untrustworthy.

Centralized infrastructure can provide economies of scale, reliability, the capacity to deliver public services, and computing resources that individuals would struggle to support independently.

The issue is that centralized services should not become people's only option for participating in digital society.

We hope to see more diverse ways of organizing technology among individuals, communities, businesses, and public institutions.

Individuals can own their computing environments; communities can jointly maintain open software and shared resources; businesses can provide high-quality paid services; and public institutions can safeguard competition, interoperability, and basic digital rights through sound institutional arrangements.

In this sense, we believe the Personal AI Computing movement has clear public demands.

We support open standards and Data Portability.

We support core security mechanisms that can be independently audited.

We support necessary public oversight of opaque data collection, automated decisions that cannot be explained, and abuses of platform control.

We support research into rights of digital exit, mechanisms for withdrawing authorization, and data migration mechanisms that are practicable for ordinary consumers.

We also believe that control over personal data is not an unlimited right.

A private recording may contain another person's secrets; family photographs may involve the interests of minors; work documents may carry legal or contractual duties of confidentiality.

Technical systems should respect other people's privacy, legitimate rights and interests, and applicable law. They cannot treat the wishes of the person holding the data as overriding permission.

Moreover, if Personal AI Computing ultimately belongs only to the few who can buy expensive equipment, understand complex network configurations, and maintain servers, it will fall far short of the personal computing revolution we describe.

Affordability, accessibility, simpler maintenance, and secure design for nontechnical users are therefore not concerns to be left until commercialization.

They are part of the movement itself.

> **A technology that truly advances freedom should not require everyone to become an engineer first.**

07 CHAPTER SEVEN

An Open Ecosystem, Not Another Walled Garden

We do not believe the next generation of the personal computing ecosystem should be designed entirely by a single company.

This field encompasses operating systems, network protocols, storage architectures, model runtimes, data connectors, security engineering, human-computer interaction, and public governance.

No company can correctly anticipate every technological path in advance.

We therefore encourage beginning with architectures that are open, replaceable, and composable.

Wherever possible, devices should use mature, general-purpose communication technologies rather than depend on unnecessary proprietary connection standards.

Different models should be replaceable through compatible interfaces.

Data formats should support migration.

Personal identity and permission systems should be able to outlast the lifecycles of particular products.

Important security designs should be subject to public discussion and independent verification.

We welcome participation from free software, open-source software, commercial products, research institutions, and individual developers.

We do not require every component to adopt the same business model, but we hope that the core mechanisms of interoperability will not be permanently closed off by a handful of vendors.

Openness does not mean neglecting security, nor does it mean that every experimental feature must be exposed directly to ordinary consumers.

Mature products can offer rigorously tested default configurations while preserving ways for capable users to inspect and modify the system.

The openness we advocate is intended to make technical systems understandable, replaceable, and repairable, and to allow them to endure after their original developers have left.

> **We hope to build a computing ecosystem that allows companies to succeed without requiring users to remain dependent on successful companies forever.**

08 CHAPTER EIGHT

From Ideas to the First Working Projects

Any technological movement that fails to produce things that actually work will ultimately remain a matter of words alone.

We therefore believe the movement's early goal should be neither to create an all-encompassing new operating system immediately nor to announce that the ultimate hardware form has already been found.

A more reasonable starting point is to establish a series of independently verifiable technical capabilities for Personal AI Computing.

We suggest exploring the following early projects:

An open personal data connection layer.
Allow AI Agents to securely retrieve information from data sources that users have authorized, without unconditionally centralizing all original data.

A model router aware of privacy constraints.
Select execution paths between local and remote compute according to task requirements, data sensitivity, cost, and model capabilities.

An independent AI Agent authorization gateway.
Provide AI Agents with task-level permissions, confirmation for sensitive operations, credential revocation, and execution auditing.

A portable format for long-term personal context.
Explore how to preserve personal knowledge, events, preferences, and authorization records while allowing correction, forgetting, and migration across models.

A management interface that ordinary people can understand.
Let users know where their data is, which services are using it, what operations have taken place, and how to change the system's behavior through simple interactions.

These projects can initially run on existing personal computers, NAS devices, mini servers, or virtualized environments.

We do not need to invent a new computer before we can begin exploring a new paradigm of personal computing.

At this stage, we place particular importance on verifiable results:

Can the system handle tasks correctly when a device goes offline? Can it block unauthorized data access? Can it resist typical malicious prompt injection? Can it preserve personal context after a change of model? Can ordinary users understand a permission request?

The answers to these questions matter more than any grand forecast of the future size of the market.

Only when these foundational capabilities are sufficiently reliable should we go on to explore dedicated hardware, standardized device certification, home computing clusters, and complete products for the general public.

09 CHAPTER NINE

This Movement Must Not Become Another Technological Utopia

We remain optimistic about the future of artificial intelligence, but we do not believe that technology necessarily brings social progress.

Personal AI systems may lower the barriers to knowledge work, but they may also deepen inequalities in capability and resources.

Long-term memory may help people understand themselves better, but it may also harden identities, encourage excessive dependence, and enable continuous surveillance.

Automation may give people more free time, but it may also gradually erode their ability to exercise judgment over critical matters.

Local computing may reduce some risks of data leakage, but it cannot automatically resolve software vulnerabilities, device theft, malicious models, or supply-chain attacks.

We must acknowledge these contradictions.

We should also give serious consideration to the energy consumption, electronic waste, and allocation of hardware resources associated with AI computing at scale.

Good Personal AI Infrastructure should extend the useful life of existing devices wherever possible, rather than forcing everyone to replace hardware frequently in pursuit of ever higher computing specifications.

We do not seek to involve AI in every detail of human life.

We seek to ensure that people can obtain intelligent assistance when they need it, and live undisturbed when they do not.

Nor do we believe that people must record every experience in their lives to be full participants in Personal AI Computing.

Choosing not to record, not to enable long-term memory, or not to allow certain devices to connect are equally choices that deserve respect.

A truly human-centered technology should allow people to refuse it.

> **We must not create, in the name of liberating individuals, a system that makes it even harder for them to leave.**

10 CHAPTER TEN

Our Shared Commitments

We do not know where the most important artificial intelligence models of the future will run.

They may run in the public cloud, on home computing equipment, or deliver services through computing architectures that we cannot yet accurately foresee.

We do not know whether the most successful personal AI product of the future will be a machine, an operating system, a communication protocol, or an intangible computing environment composed of many devices.

Nor do we know whether, decades from now, Personal AI Computing will become infrastructure taken for granted in social life, as personal computers did before it.

But we are willing to begin today to establish the technical conditions for such a future.

To that end, we make the following commitments:

1. **Make human autonomy, rather than system autonomy, the ultimate goal of technological development.**
2. **Measure personal digital freedom by effective control, rather than by abstract slogans of data ownership.**

3. **Uphold openness and interoperability as principles, enabling users to leave any single technology provider.**
4. **Build on security by default and minimal authorization, refusing to base convenience on unlimited trust.**
5. **Ease users' burdens through explainable, correctable AI assistance without depriving them of the final say.**
6. **Test the value of technology against the real needs of ordinary people, rather than treating architectural complexity as proof of technological advancement.**
7. **Replace blind certainty about the future of technology with continuous experimentation, public discussion, and verifiable engineering results.**

We welcome people from different backgrounds to take part in this exploration.

Engineers can develop protocols, runtimes, and security components.

Designers can reimagine how people interact with personal AI systems.

Researchers can explore long-term memory, privacy reasoning, trusted computing, and human-AI collaboration.

Those working in law and the social sciences can help us understand data rights, public responsibilities, and the effects of AI Agents on social institutions.

Ordinary users are equally important participants in this movement. Their real experiences of privacy, trust, convenience, and autonomy should continually shape technical design.

We hope to form an open community that continually produces working creations, knowledge, and public discussion, rather than a closed circle organized around a few technological authorities.

Perhaps one company, or many, will emerge with Personal AI Computing at their core.

We welcome the emergence of such companies.

But a company's commercial success should not be regarded as the movement's ultimate purpose.

If one day any ordinary person can freely choose their AI services, safely use the data they have accumulated over time, continue their work across different devices, and truly stop an AI's involvement in their life when needed, we would consider the movement a success, even if those capabilities were jointly provided by many different organizations.

For what we truly wish to change has never been which company owns the largest model, or which device has the most computing cores.

What we wish to change is **the relationship between people and AI computing infrastructure**.

11 EPILOGUE

The Next Personal Computer May Have No Fixed Form

Half a century ago, a group of engineers and computer enthusiasts brought microcomputers whose uses were not yet fully defined into their garages, workshops, and living rooms.

They did not know what kind of industry personal computers would ultimately become, nor how billions of people would one day work, learn, communicate, and create through computing devices.

One important thing they did was to stop treating the idea that computers could belong only to large institutions as an unchangeable premise.

Today, we too wish to ask a question:

Why must AI systems capable of understanding individuals' lives, accessing their data, and acting on their behalf remain forever dependent on a handful of centralized platforms?

Why can individuals not own their own AI infrastructure, managing data, models, compute, and AI Agents as they manage their own computers?

We acknowledge that these questions do not yet have complete answers.

It is precisely because the answers remain unsettled that more people should begin building now.

We need new protocols, new software, and new security architectures, as well as new design languages and social consensus.

We need people who can imagine boldly, and engineers willing to test repeatedly, fix flaws, and acknowledge failure.

We need ambition for technology, alongside vigilance toward the harm it may cause.

We hope that when people look back on this period, they will see that artificial intelligence did not inevitably lead to a world in which all AI capabilities and personal information were permanently centralized.

People tried another path, and built it.

On that path, intelligence may come from afar, but power need not remain far away.

Data may cross devices, but individuals need not surrender their boundaries.

AI Agents may act for people, but people need not hand over their will to AI Agents.

If the previous personal computing revolution enabled more people to own a computer of their own for the first time, we hope the next revolution will enable more people to truly own intelligence of their own.

This is what we mean by the PC Moment of AI.

Computing should empower individuals.

Intelligence should serve people.

Everyone should be able to help create the future.

AN OPEN INVITATION · 2026

We are not waiting for the next personal computer to be released.

We want to help invent it ourselves.

Personal AI Computing Movement · Early Draft of Principles

An invitation to developers, designers, researchers, and everyone who believes computing technology should expand individual freedom.

This text is a draft for open discussion. Its principles and technical approaches should withstand criticism, experimentation, and subsequent revision.
